Sample Question and Model Answer: Water Salinity Analysis

Question: Given the following data from a water sample: Conductivity: 45 mS/cm Temperature: 20°C Calculate the salinity of the water sample.

Model Answer: To calculate salinity from conductivity, we can use the practical salinity scale or a conversion factor. Convert conductivity to Practical Salinity (SP): At 20°C, the approximate relation is: $SP \approx \text{Conductivity (mS/cm)} \times 1.806$. Therefore, $SP \approx 45 \times 1.806 = 81.27$. Convert Practical Salinity to PSU (practical salinity units): Since SP is approximately equal to PSU, salinity ≈ 81.27 PSU (parts per thousand).

Final Answer: The water sample has a salinity of approximately 81.27 PSU, indicating highly saline conditions typical of seawater.

Note: Actual calculations may require calibration curves or specific formulas depending on the equipment used.

Question 1: What are the main layers of Earth's interior, and what are their characteristics?
Crust: The outermost layer, solid, relatively thin, composed mainly of rocks like granite and basalt.
Mantle: Located beneath the crust, semi-solid, extends to about 2,900 km depth, composed of silicate rocks rich in magnesium and iron.
Core: Divided into outer (liquid iron and nickel) and inner (solid iron and nickel) core, responsible for Earth's magnetic field.
Answer: The Earth's interior consists of three main layers: the crust, which is the Earth's outer shell; the mantle, a thick layer of semi-solid rock beneath the crust; and the core, made up of a liquid outer core and a solid inner core. These layers vary in composition, state, and physical properties, playing crucial roles in Earth's geology and magnetic field.

Question 2: Explain how seafloor spreading contributes to plate tectonics.
Answer: Seafloor spreading occurs at mid-ocean ridges where magma rises from the mantle, creating new oceanic crust. As new crust forms, it pushes older crust away from the ridge, causing tectonic plates to move apart. This process explains the creation of new ocean floors and helps drive plate movements, leading to phenomena such as earthquakes and volcanic activity.

Question 3: What are the differences between weather and climate?
Weather: Short-term atmospheric conditions such as temperature, humidity, precipitation, wind, and cloudiness observed over hours or days.
Climate: The long-term average of weather patterns in a region over extended periods (typically 30 years or more).
Answer: Weather refers to immediate atmospheric conditions, which can change rapidly, whereas climate describes the long-term patterns and averages of weather in a specific area. Understanding both is vital for predicting weather events and studying environmental changes.
